How to Give a Subcutaneous Injection via a Cannula Using No Needle Technique

1. Wash your hands with soap and water and dry well.

2. Gather all the equipment required and take the prepared syringes and a sharps or hard walled container to the person.

3. Check the injection site for redness, tenderness, swelling or leaking.

4. Remove the red cap or blunt needle from the syringe and place the blunt needle directly into the sharps or hard walled container. Remove the red cap or rubber bung (using a screwing motion) located at the end of the cannula.

5. Swab the end of the cannula (optional), and then insert the syringe, containing the medication, into the cannula.

6. Slowly push the plunger of the syringe until the barrel is empty, then remove the syringe. Insert the second syringe and repeat the process as necessary. Flush the cannula with 0.5ml sterile normal saline. Replace the red cap of the rubber bung on the end of the cannula.

7. Record the date and time the medication was given. Observe the effect of the medication and record the results.

8. Contact your nursing service/doctor if you have any concerns.
